Each stage of this multiplier is a doubler circuit and is made up of (2) Capacitors and (2) Diodes. On the positive half-cycle of the input, the capacitors charge in parallel to the peak value of the voltage presented through the forward biased diode. The other diode is reversed biased. Each cap charges to 8484 peak volts.

The plug gap then presents an open circuit to the system. The points close and dc current flows once more. The charge or energy stored in the capacitor now flows out of the capacitor through the closed points. Capacitors block direct current and pass alternating current by charging and discharging throughout each cycle.

The ignition system is one of the most important systems used in the I.C. engines. The spark-ignition engine requires some device to ignite the compressed air-fuel mixture. The ignition takes place inside the cylinder at the end of the compression stroke, the ignition system serves this purpose.

typically, externally fused capacitor banks have higher failure voltages and currents than fuseless or internally fused banks because an external fuse blowing causes the loss of an entire unit. As a point of reference, fuseless capacitor banks have a unit construction, as shown in Fig. 1 [1]. Capacitor Unit Element Case Internal Discharge ...
