Other errors can be introduced ...

When light strikes the surface of a solar cell, some photons are reflected, while others pass right through. Some of the absorbed photons have their energy turned into heat. The remainder have the right amount of energy to separate electrons from their atomic bonds to produce charge carriers and electric current.

For instance, the 100-watt solar panel from our example has a  $V_{mp}$  rating of 17.8 Volts, which means that under the STCs, this solar panel will measure 17.8 Volts across its terminals when it's producing 100 Watts of power.
