The Bernoulli principle is often given as the reason why wings can provide lift and airplanes can fly. It relates pressure and flow speed Footnote 1 and thus plays an important role in determining aerodynamic forces. The principle states that in a "nice" flow situation, the pressure rises when the medium is slowed and vice versa.

1 Rule of thumb: Air flow (cfm) is proportional to motor speed, and static pressure varies with the motor speed squared (if the speed increases by 2%, the pressure increases by 4%). The PSC motors tested above perform with increased efficiency, equal or increased power output, and lower starting and running current than the split phase motors.

An air capacitor is a capacitor that uses air as a dielectric, and this capacitor can be designed in fixed or variable capacitance form. The fixed capacitance type is not often used because there are different types of fixed capacitors with much better characteristics than it, so the variable capacitance form is more frequently used due to its simple construction.

The types of capacitors are categorized as follows based on polarization: Polarized; Unpolarized; A polarized capacitor, also known as an electrolytic capacitor, is a crucial component in an electronic circuit. These capacitors are used to achieve high capacitive density. Unpolarized capacitors are preferred over fully charged capacitors.

After impressing air pressure into the part under test (WORK), the change in internal pressure is measured to evaluate for leaks. A non-leaking standard (MASTER) is used, and is pressured at the same time as WORK.

Capacitive: Capacitive pressure sensors use a diaphragm that is deflected by the applied pressure to create a variable capacitor to detect strain due to applied pressure. As pressure is applied, the external pressure compresses the diaphragm, and the capacitance value decreases.

Static pressure transducers measure the pressure of a fluid when it is at rest. Static pressure transducers are the most commonly used pressure monitoring devices. When a fluid exerts pressure on the pressure transducers, the strain gage (or the sensor) within it gets deformed. This deformation results in voltage variations.

Initially, a capacitor with capacitance (C_0) when there is air between its plates is charged by a battery to voltage (V_0). When the capacitor is fully charged, the battery is disconnected. A charge (Q_0) then resides on the plates, and the potential difference between the plates is measured to be (V_0).
