When a capacitor is connected to a power source, such as a battery, it begins to accumulate or "store" charge. This process is known as capacitor charging. The power source provides a potential difference across the capacitor's plates, causing current to flow.

As we saw in the previous tutorial, in a RC Discharging Circuit the time constant (τ) is still equal to the value of RC . Then for a RC discharging circuit that is initially fully charged, the voltage across the capacitor after one time constant, 1τ , has dropped by 63% of its initial value which is $1 - 0.63 = 0.37$ or 37% of its final value.
