Derivation of Energy Stored in a Capacitor [Click Here for Sample Questions] The process of charging a capacitor is equivalent to that of transferring charges from one plate of the capacitor to another plate. Some work must be done in charging a capacitor and this work done is stored as electrostatic potential energy in the capacitor.

The energy U stored in a capacitor is equal to the work W done in separating the charges on the conductors. The more charge is already stored on the plates, the more work must be done to separate additional charges, because of the strong repulsion between like charges. At a given voltage, it takes an infinitesimal amount of work $dW = V dQ$ to ...

Upon integrating Equation (ref{5.19.2}), we obtain $[Q=CV \left(1-e^{-t/(RC)} \right)]$.label{5.19.3} Thus the charge on the capacitor asymptotically approaches its final value (CV), reaching 63% ($1 - e^{-1}$) of the final value in time (RC) and half of the final value in time ($RC \ln 2 = 0.6931, RC$).. The potential difference across the plates increases at the same rate.

He says that when the capacitor is shorted the potential at each plate changes by $V/2$ (from 0 to $V/2$ on one side and from V to $V/2$ on the other), so by substituting in $V/2$ into the equation he gets $E = 1/2 QV$, the capacitor energy equation.

The capacitance C increases linearly with the area A since for a given potential difference V , a bigger plate can hold more charge. On the other hand, C is inversely proportional to d , the distance of separation because the smaller the value of d , the smaller the potential difference ...
