

When the EV battery exceeds the charging threshold, a BSS swaps out the depleted battery (DB) for a fully charged battery (FB) before placing the battery in the charging station (BCS). When the charging is finally completed, the BCS sends it back to the BSS for swap in EVs. If the BSS does not have any FB, EVs need to wait.

Additional contributing factors might include battery charging efficiency, voltage matching, conversion losses,

and potential system limitations [22, 25]. Collectively, these elements can result in a situation where an increase in solar irradiance does not translate to a proportional increase in stored energy in the ESS.

It is this voltage the charger will measure at the battery output terminals when the charging process begins. This voltage will influence the initial charge-current inrush and the final charging level. Considering 1 and 2 above, we now decide to charge the battery using a constant voltage of 2.4 volts per cell (14.4V per battery).

In stand-alone systems, the output voltage of the photovoltaic (PV) array should match that of the battery storage capacity and from this an appropriate charge controller can be selected to ensure that the charge controller delivers the appropriate amount of charge when needed and will not overcharge the batteries.
