Depending on how large we expect the voltage to scale, we need a capacitor with a voltage rating matched for that voltage. So we can decide a rough estimate for how high we believe the voltage we reach. Say, we have good estimates the voltage will peak no higher than 30V, then for that application, a 50V voltage capacitor will suffice.

capacitor is called a "tuning capacitor" or a "resonating capacitor." The electrical equivalent of the parts in Fig. 1 is offered in Fig. 2. The arrow through the capacitor indicates it is adjustable. The illustration at A represents what is known as a parallel-resonant circuit, since the coil and capacitor are in parallel.

R_4 - a variable non-inductive resistance parallel with variable capacitor C_4 zero current passes through the detector, which shows that the potential across the detector is zero. At balance condition $Z_1/Z_2 = Z_3/Z_4$ $Z_1 Z_4 = Z_2 Z_3$

The capacitor C_2 is the standard capacitor and C_4 is a variable one. The resistance R_3 is a non-inductive resistance and R_4 is a variable non-inductive resistance connected in parallel with a capacitor C_4 . The supply is connected between nodes A and C while the detector is connected between B and D. From the above figure, the impedances of the ...

One is that the maximum rated voltage of a parallel connection of capacitors is only as high as the lowest voltage rating of all the capacitors used in the system.
