Can you determine which capacitor has more charge? Discharge each of the two charged capacitors through the charge pump, one at a time, to measure how much charge it has. Connect the negative terminal of the capacitor to the positive terminal of the charge pump, and positive to negative. Then the discharge rate is 1 mC/s.

When a circuit is made that allows a capacitor to discharge, the electric field in the wire causes electrons to flow from the wire into the positively charged plate (thus reducing it's net positive charge. At the same time the electric field in the wire causes electrons in the wire to move toward the positive plate of the capacitor.

Two parallel-plate capacitors, 6.0 mF each, are connected in parallel to a 10 Vbattery. One of the capacitors is then squeezed so that its plate separation is 50.0% of its initial value. Because of the squeezing, (a) How much additional charge is transferred to the capacitors by the battery?

If too much charge is placed on a capacitor, the material between the two plates will break down, and a spark will usually damage the capacitor as well as discharge it. We can easily calculate the capacitance of a parallel plate capacitor.
