Fit the curve to the known equation for the charging of a capacitor through a known resistance to a known voltage:  $V(t) = V * (1 - \text{EXP}(-t / (R * C)))$ . Use Excel or similar and try different values of  $C$  until you find one that adequately fits your empirical data, then that must be your best guess at  $C$ .

atmel defines the stray capacity as being from xtal terminal to gnd. NXP defines the stray capacity as parallel to the crystal. This gives. Stray capacities:  $C_{atmel} = 2 C_{nxp}$ . so it is all a matter of definition. Anyway there are typically some "handwaving" involved in stray estimates anyway.
