The proposed compensation method can be easily implemented by a digital PFC controller. In a traditional PFC with average current-mode control, the current reference is generated by: $I_{REF} = A \cdot B \cdot C$ (8) where A = voltage loop output, $B = 1/\sqrt{2} \cdot AC_{RMS}$, and C = the sensed $V_{AC}(t)$ input voltage. However, if the circuit contains reactive components, the voltage and current waveforms will be "out-of-phase" by some amount determined by the circuit's phase angle. If the phase angle between the voltage and the current is at its maximum of 90°, the volt-amp product will have equal positive and negative values.
