Energy density is how much energy a battery contains in proportion to its volume (Wh/L). Another way to think of energy density is as the amount of runtime in relation to the battery's size. Higher energy density means a smaller battery that can store more energy which is always a good thing. Battery power is defined in Wh (Watt Hours).

If you charge your battery pack to 4 volts per cell and stop using it when it reaches around 2.8 volts per cell, then your battery pack will have a lifespan that is 2 to 3 times longer while having a capacity only around 20 percent less. Voltage of one battery = V Rated capacity of one battery : Ah = Wh C-rate : or Charge or discharge current I : A Time of charge or discharge t (run-time) = h Time of charge or discharge in minutes (run-time) = min Calculation of energy stored, current and voltage for a set of batteries in series and parallel

A higher battery bank voltage will require a lower energy storage capacity, while a low voltage will demand a higher energy storage capacity. For this example, let's assume that there is a 48V nominal voltage and a 50% DOD.

The power output of the battery pack is equal to: $P_{\text{pack}} = I_{\text{pack}} \times U_{\text{pack}} = 43.4 \text{ W}$. The power loss of the battery pack is calculated as: $P_{\text{loss}} = R_{\text{pack}} \times I_{\text{pack}}^2 = 0.09 \times 4^2 = 1.44 \text{ W}$. Based on the power losses and power output, we can calculate the efficiency of the battery pack as: $\eta_{\text{pack}} = (1 - P_{\text{loss}} / P_{\text{pack}}) \times 100 = (1 - 1.44 \dots$

Check the results per type of battery.
