This measures the internal resistance of the battery, which increases as the battery ages and wears out. Impedance tests are typically done with a 1kHz AC signal at low currents ($\leq 10\text{mA}$). Nickel-based batteries: The internal resistance in these types of batteries decreases throughout discharge until about halfway through the discharge cycle, then it steadily rises up again.

Internal resistance as a function of state-of-charge. The internal resistance varies with the state-of-charge of the battery. The largest changes are noticeable on nickel-based batteries. If we do that, we will get the voltage drop across the internal resistance. $V_{\text{internal}} = 3.85 - 3.72 = 0.13\text{V}$. Now we have the voltage drop across the internal resistor, we can just divide it with the calculated current and we will get the internal resistance. $\text{ISR} = (V_{\text{drop-internal}} / \text{Current}) = 0.13 / 3.236 = 0.04017 \text{ ohms}$. The calculated internal ...
