The capacitor on the left is of a ceramic disc type capacitor that has the code 473J printed onto its body. Then the 4 = 1 st digit, the 7 = 2 nd digit, the 3 is the multiplier in pico-Farads, pF and the letter J is the tolerance and this translates to: 47pF * 1,000 (3 zero''s) = 47,000 pF, 47nF or 0.047uF the J indicates a tolerance of +/- 5%. Then by just using numbers and letters as codes ...

The multilayer ceramic capacitor and leaded film capacitor show roughly the same characteristics up to the resonance point, but the self-resonant frequency is higher and |Z| in the inductive region is lower in the

multilayer ceramic capacitor. This is because, in leaded film capacitors, the inductance is only as large as that due to the lead wire.

I"ve read that these small brown ceramic capacitors are most likely unpolarised, to my knowledge meaning they can be turned both ways and still do their job just fine. But using my multimeter measuring capacitance, gives the result 8.400 uF and while reversed on the same capacitor gives me the result 26.60 uF.
