In the same way, if metering is carried out at low voltage, the share of the reactive power consumed by the MV/LV transformer is added to the billed energy on a fixed basis. For example, if the permitted value of $\tan\phi$ changes to 0.31, the amount of reactive energy billed E_r will become:

The proposed compensation method can be easily implemented by a digital PFC controller. In a traditional PFC with average current-mode control, the current reference is generated by: $I_{REF} = A \cdot B \cdot C$ (8) where A = voltage loop output, $B = 1/\sqrt{2} \cdot AC_{RMS}$, and C = the sensed $V_{AC}(t)$ input voltage. We define the reactive power to be positive when it is absorbed (as in a lagging power factor circuit).. a. Pure capacitance element - For a pure capacitance element, $P=0$ and I leads V by 90° ; so that complex power is: $S = jQ = (V \angle 0^\circ) (I \angle 90^\circ)$; $S = V \cdot I \angle 90^\circ$; $S = -jV \cdot I$. Thus the capacitance element generates reactive power.
