

The technique of laying out solar cells in a module so that their edges overlap like shingles on a house roof is called »shingling« With the shingled layout, there are fewer gaps between the individual solar cells so more of the sunlight that is incident on the module can be absorbed.

Since more of the module can be covered by solar cells, shingled solar panels is a very suitable method for bifacial modules. More light can be absorbed and "back-escape" losses can be reduced, which normally occur when light passes through the gaps in traditional bifacial modules.

The module dimensions are 2,382 x 1,134 x 30 mm, and it weighs 32.3 kg. The 2 mm double-glass module features a bifaciality factor of 80% ± 5%. The module comes with a 30-year linear power warranty, less than 1% degradation in the first year, and a maximum of 0.4% annual degradation thereafter.

Significant progress in the development and commercialization of electrically conductive adhesives has been made. This makes shingling a very attractive approach for solar cell interconnection. In this study, we investigate the shading tolerance of two types of solar modules based on shingle interconnection: first, the already commercialized string approach, ...

Furthermore, shingled modules have upwards of 34 cells connected in series per string compared to 20 or 24 cells per string typically found in conventional 60 or 72 cell modules, respectively. An increase in series connected cells leads to the development of higher reverse voltages and subsequently greater heat dissipation in the shaded cell ...
