The basic function of a capacitor is to store energy in an electric field. Capacitors store energy and release it when necessary, in contrast to resistors, which limit the flow of current. A capacitor is made up of two conductive plates, which are separated by an insulating material called a dielectric.

If batteries or capacitors are part of a closed circuit, electrical current flows. Unlike batteries, however, capacitors do not free up electrons. They only store them. The tutorial below demonstrates a capacitor functioning in a direct current circuit that powers an electric motor used to lift a small weight.

The rating or setting of the OCPD must be as low as practicable [460.8(B)]. If you install a capacitor on the load side of the motor overload device, the rating or setting of that device must be based on the improved power factor of the motor circuit [460.9]. Bond capacitor cases to the equipment grounding (bonding) conductor [460.10].
