Thats for the in depth reply. I actually just got a new 118 fast charger last week and put it on there and it's charging! If I put it back to the original charger, it still does hot/cold delay. The original charger still charges all my other batteries just fine though, including another 6AH battery.

Temperature: Extreme ambient temperatures, both hot and cold, can reduce the charging rate or even prevent the battery from accepting a charge altogether. State of charge: In general, the acceptance rate of an EV battery is highest when the battery is at a low state of charge (SoC) and decreases as the battery gets closer to its maximum SoC ...

Both vehicles start charging. Tesla A's battery is cold, so 4.05 kWh are used to raise its temperature before before charging speed increases while adding back the 40.5 kWh necessary to bring it from 30% to 80% charge. 44.55 (4.05 + 40.5) kWh are used for that charging session. ... As a result, new energy vehicles are increasingly being developed with a focus on enhancing the rapid and uniform heat dissipation of the battery pack during charging and ...

If a battery pack gets too hot, it has the potential to combust, which nobody wants. But when we're talking about charging an EV in cold weather, the goal is to warm the battery pack up to its optimal temperature range. The act of charging a battery will cause it to warm up on its own, but since an overly cold battery cannot reach its maximum ...

That energy, through convection of the hot air mass, gets pumped into ...

Another big difference is the speed of charging. DC chargers have a converter inside them. This means power from the DC charging station goes straight into the battery, skipping the car's onboard charger. This makes charging with direct current ten times faster than charging with alternating current. 5. Charging Curve Shape:
