What Causes Excessive Corrosion on Positive Battery Terminal? When battery corrosion builds up on the positive battery terminal, it creates a barrier between the terminal and the cable connector. This can prevent electrical current from flowing freely between them, causing excessive voltage drop and increased resistance.

As you can see, from the below power loss equation, the power is proportional to the square of the current. So, if the current increases, the power losses will increase much faster. As we know, $Power = I^2 \cdot R$, This means, the higher the current the higher energy loss in the conductor in the form of heat. As I mentioned above.

Yes, a starter should always have power because it needs a high current to turn over the engine. This current can only be provided if the battery has sufficient power. A discharged or weak battery cannot power the starter with enough current to turn over the engine. This is one of the reasons some people attach a car without starting the starter.
