The main disadvantage related to the use of lead-acid batteries is its degradation (aging), that occurs as a function of discharge cycles, depth of discharge, charging voltage, and ambient temperature [13], [14]. Thus, the estimation of autonomy is a useful tool to anticipate problems related to energy supply.

In EVs, hybrid systems such as lithium-ion capacitors [] can be assembled, but presently, lead acid, Ni-MH, and Ni-Cad batteries remain more prevalent "s worth noting that Ni-MH and Ni-Cad batteries [] are susceptible to memory effects and are less environmentally friendly compared to lithium-ion batteries [27,28,29,30] should be noticed that nowadays, ...

1. Collection: The initial step in the battery recycling process entails the collection of discarded lead batteries from various disposal points.

Lead-Acid Battery Cells and Discharging. A lead-acid battery cell consists of a positive electrode made of lead dioxide (PbO_2) and a negative electrode made of porous metallic lead (Pb), both of which are immersed in a sulfuric acid (H_2SO_4) water solution. This solution forms an electrolyte with free (H^+ and SO_4^{2-}) ions.

This led to many profitable businesses and the recycling of other batteries. Figure 1: Lead acid are the most recycled batteries. Recycling is profitable [1] In late 2013, smelters started to report an increased number of Li-ion batteries being mixed in with lead acid, especially in starter batteries.
