Batteries have resistance, which loses energy in heat loss due to I^2R dissipation. But supercapacitor's answer sort of touches on two other effects: (1) higher current use causes the battery voltage to reach its "end-of-discharge" voltage more quickly (you think it's empty sooner than it actually is) due to IR drop, and (2) higher current use ...

Voltage is defined as the electrical potential energy divided by charge: $V = \frac{PE}{q}$. An electron volt is the energy given to a single electron by a voltage of 1 V. So the voltage here is 2 V, since 2 eV is given to each electron. It is the energy produced in each molecular reaction that produces the voltage.
