According to the physical formula $R=U/I$, the test equipment makes the lithium ion battery in a short time (generally 2-3 seconds) to force through a large stable DC current (generally use 40A ~ 80A large current), measure the voltage at both ends of the lithium ion battery at this time, and calculate the lithium ion battery ...

o DC internal resistance, or DC-IR, is a large signal method that uses a high current DC pulse stimulus to measure a cell's internal resistance. The duration of the pulse can be related to the inverse of the test frequency used in AC measurement methods, up to the point where cell discharge starts becoming significant, as was shown here.

Direct Current Internal Resistance, DCIR or DCR can be measured with a battery tester by applying a low current followed by higher current on the battery within a short period, and then record the changes of battery voltage ΔV and current ΔI . Based on Ohm's Law, $DCIR = \Delta V / \Delta I$. The AC Impedance and DCIR both indicate battery's power ...

What is the normal internal resistance of a 2v DC battery pack

High resistance causes the battery to heat up and the voltage to drop. The equipment cuts off, leaving energy behind. A battery's State of Health (SoH) is 100% when new, and decreases from there, with its internal resistance increasing and capacity decreasing. A key factor in the design of battery packs is the internal resistance R_{int} [Ω]. Internal resistance is a natural property of the battery cell that slows down the flow of electric current. It's made up of the resistance found in the electrolyte, ...

Temperature of a battery will change the reading and testers aren't that accurate. But still the numbers are pretty good. Also sometimes with bad battery internal resistance measurement that's done at high frequency can give good numbers. It's not super uncommon to see a really bad battery giving out numbers that are better than new.

Batteries will always have some resistance. Though the internal resistance may be or appear low, around 0.1 Ω for an AA alkaline battery, and about 1 Ω to 2 Ω for a 9-volt alkaline battery, it can cause a noticeable drop in output voltage if a low-resistance load is attached to it.

It's worth noting that the internal resistance of a battery can vary depending on factors such as the age and condition of the battery, its temperature, and the load being applied to it. Additionally, the internal resistance of a battery can be affected by the type of battery chemistry used, such as lead-acid, lithium-ion, or nickel-metal hydride.

Consider a two way radio. With high internal resistance, it can run in stand by for a long time since the radio isn't drawing much current. Then, you hit the transmit button and the radio shuts off because the voltage dropped at high current because of the internal resistance of the battery. So, the internal resistance is a necessary indicator ...

How high is too high? Your example would be too high for most. The peak power from a 144V pack with 0.2 Ω internal resistance is 26 kW. So that would be about 26 hp to the wheels. This would be insufficient power for a passenger EVcar to drive at highway speeds reasonably well. Battery internal resistance relates to the specific power or kW/kg.
