The requirements for negative electrodes are many and depending on the priority given to them, the negative electrode materials discussed meet them only partly. There are three main groups of negative electrode materials for Li-ion batteries. The materials known as insertion materials are Li-ion batteries' "historic" electrode materials.

The developed battery concept is based on a composite material and has carbon fibre as both the positive and negative electrodes - where the positive electrode is coated with lithium iron phosphate. When the previous battery concept was presented, the core of the positive electrode was made of an aluminium foil.

The negative electrode is one of the key components in a lead-acid battery. The electrochemical two-electron transfer reactions at the negative electrode are the lead oxidation from Pb to PbSO₄ when charging the battery, and the lead sulfate reduction from PbSO₄ to Pb when discharging the battery, respectively.

An electrode is an electrical conductor used to make contact with a nonmetallic part of a circuit (e.g. a semiconductor, an electrolyte or a vacuum). The word was coined by the scientist Michael Faraday from the Greek words elektron (meaning amber, from which the word electricity is derived) and hodos, a way.
